Waze Project

Course 3 - Go Beyond the Numbers: Translate Data into Insights

Your team is still in the early stages of their user churn project. So far, you've completed

a project proposal and used Python to inspect and organize Waze's user data.

You check your inbox and notice a new message from Chidi Ga, your team's Senior Data

Analyst. Chidi is pleased with the work you have already completed and requests your

assistance with exploratory data analysis (EDA) and further data visualization. Harriet

Hadzic, Waze's Director of Data Analysis, will want to review a Python notebook that

shows your data exploration and visualization.

A notebook was structured and prepared to help you in this project. Please complete the

following questions and prepare an executive summary.

Course 3 End-of-course project: Exploratory data analysis

In this activity, you will examine data provided and prepare it for analysis.

The purpose of this project is to conduct exploratory data analysis (EDA) on a provided

dataset.

The goal is to continue the examination of the data that you began in the previous

Course, adding relevant visualizations that help communicate the story that the data

tells.

This activity has 4 parts:

Part 1: Imports, links, and loading

Part 2: Data Exploration

Data cleaning

Part 3: Building visualizations

Part 4: Evaluating and sharing results

Follow the instructions and answer the question below to complete the activity. Then, you will complete an executive summary using the questions listed on the PACE Strategy Document.

Be sure to complete this activity before moving on. The next course item will provide you with a completed exemplar to compare to your own work.

Visualize a story in Python

Task 1. Imports and data loading

For EDA of the data, import the data and packages that will be most helpful, such as pandas, numpy, and matplotlib.

```
In [1]: import pandas as pd
   import matplotlib.pyplot as plt
   import numpy as np
   import seaborn as sns
```

Read in the data and store it as a dataframe object called df.

```
In [2]: # Load the dataset into a dataframe
df = pd.read_csv('waze_dataset.csv')
```

Answers:

- 1. The data is already in a structured format. Each row represents a user.
- 2. Yes, 700 rows have label missing. Other variables have no missing values.

Task 2. Data exploration and cleaning

Consider the following questions:

- 1. Given the scenario, which data columns are most applicable?
- 2. Which data columns can you eliminate, knowing they won't solve your problem scenario?
- 3. How would you check for missing data? And how would you handle missing data (if any)?
- 4. How would you check for outliers? And how would handle outliers (if any)?

Answers:

- Since we are interested in user churn, the label column is essential. Besides label, variables that tie to user behaviors will be the most applicable. All variables tie to user behavior except ID.
- 2. ID can be dropped from the analysis since we are not interested in identifying a particular user. ID does not provide meaningful information about the churn (unless ID is assigned based on user sign-up time).
- 3. To check for missing data, we can use df.info() and inspect the Non-Null Count column. The difference between the number of non-nulls and the number of rows in the data is the number of missing values for the variable.
 - If the missing data are missing completely at random (MCAR), meaning that the reason for missingness is independent of the data values themselves, we can proceed with a complete-case analysis by removing the rows with missing values. Otherwise, we need to investigate the root cause of the missingness and make sure it won't interfere with the statistical inference and modeling.
- 4. See the previous exemplar responses for the outlier question.

Data overview and summary statistics

Use the following methods and attributes on the dataframe:

- head()
- size
- describe()
- info()

It's always helpful to have this information at the beginning of a project, where you can always refer back to if needed.

In [3]: df.head(10)

Out[3]:		ID	label	sessions	drives	total_sessions	n_days_after_onboarding	total_navig
	0	0	retained	283	226	296.748273	2276

memory usage: 1.5+ MB

Consider the following questions as you prepare to deal with outliers:

- 1. What are some ways to identify outliers?
- Use numpy functions to investigate the mean() and median() of the data and understand range of data values
- Use a boxplot to visualize the distribution of the data
- 2. How do you make the decision to keep or exclude outliers from any future models?
- There are three main options for dealing with outliers: keeping them as they are, deleting them, or reassigning them. Whether you keep outliers as they are, delete them, or reassign values is a decision that you make on a dataset-by-dataset basis, according to what your goals are for the model you are planning to construct. To help you make the decision, you can start with these general guidelines:
 - Delete them: If you are sure the outliers are mistakes, typos, or errors and the dataset will be used for modeling or machine learning, then you are more likely to decide to delete outliers. Of the three choices, you'll use this one the least.
 - Reassign them: If the dataset is small and/or the data will be used for modeling or machine learning, you are more likely to choose a path of deriving new values to replace the outlier values.
 - Leave them: For a dataset that you plan to do EDA/analysis on and nothing else, or for a dataset you are preparing for a model that is resistant to outliers, it is most likely that you are going to leave them in.

Task 3a. Visualizations

Select data visualization types that will help you understand and explain the data.

Now that you know which data columns you'll use, it is time to decide which data visualization makes the most sense for EDA of the Waze dataset.

Question: What type of data visualization(s) will be most helpful?

- Line graph
- Bar chart
- Box plot
- Histogram
- Heat map
- Scatter plot
- A geographic map

Answer:

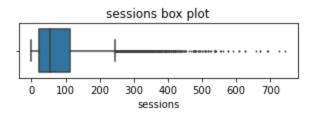

- Box plots will be helpful to determine outliers and where the bulk of the data points reside in terms of drives, sessions and all other continuous numeric variables
- Histograms are essential to understand the distribution of variables
- Scatter plots will be helpful to visualize relationships between variables
- Bar charts are useful for communicating levels and quantities, especially for categorical information

Begin by examining the spread and distribution of important variables using box plots and histograms.

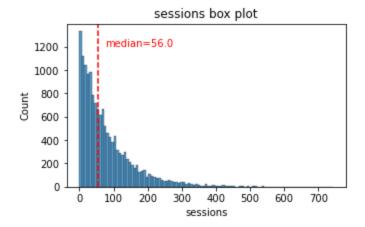

sessions

The number of occurrences of a user opening the app during the month

```
In [7]: # Box plot
plt.figure(figsize=(5,1))
sns.boxplot(x=df['sessions'], fliersize=1)
plt.title('sessions box plot');
```

```
In [8]: # Histogram
   plt.figure(figsize=(5,3))
   sns.histplot(x=df['sessions'])
   median = df['sessions'].median()
   plt.axvline(median, color='red', linestyle='--')
   plt.text(75,1200, 'median=56.0', color='red')
   plt.title('sessions box plot');
```

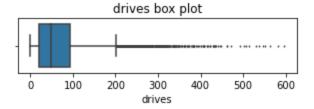

The sessions variable is a right-skewed distribution with half of the observations having 56 or fewer sessions. However, as indicated by the boxplot, some users have more than 700.

drives

An occurrence of driving at least 1 km during the month

```
In [9]: # Box plot
plt.figure(figsize=(5,1))
sns.boxplot(x=df['drives'], fliersize=1)
plt.title('drives box plot');
```

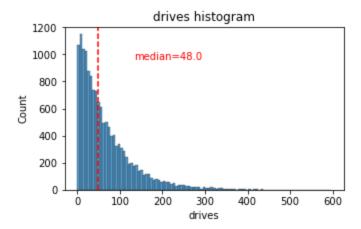

As you perform EDA, you'll find that many tasks get repeated, such as plotting histograms of features. Remember that whenever you find yourself copy/pasting code, it's worth considering whether a function would help make your work more efficient. Sometimes it's not worth it. Other times, defining a function will help a lot.

The following code block defines a function that helps plot histograms with a particular style/format using this particular dataset. You don't have to do this, but in this case it's helpful.

```
In [10]: # Helper function to plot histograms based on the
         # format of the `sessions` histogram
         def histogrammer(column_str, median_text=True, **kwargs):
                                                                       # **kwargs = ar
                                                                       # from the sns.
             median=round(df[column_str].median(), 1)
             plt.figure(figsize=(5,3))
             ax = sns.histplot(x=df[column_str], **kwargs)
                                                                       # Plot the hist
             plt.axvline(median, color='red', linestyle='--')
                                                                       # Plot the medi
                                                                       # Add median te
             if median_text==True:
                 ax.text(0.25, 0.85, f'median={median}', color='red',
                     ha='left', va='top', transform=ax.transAxes)
             else:
                 print('Median:', median)
             plt.title(f'{column str} histogram');
```

In [11]: # Histogram histogrammer('drives')

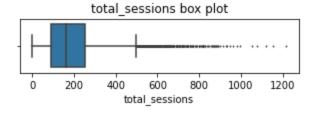

The drives information follows a distribution similar to the sessions variable. It is right-skewed, approximately log-normal, with a median of 48. However, some drivers had over 400 drives in the last month.

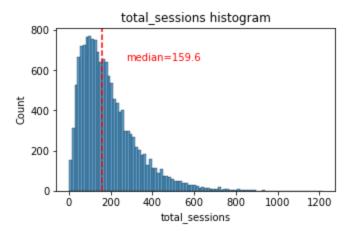

total_sessions

A model estimate of the total number of sessions since a user has onboarded

```
In [12]: # Box plot
   plt.figure(figsize=(5,1))
   sns.boxplot(x=df['total_sessions'], fliersize=1)
   plt.title('total_sessions box plot');
```

In [13]: # Histogram
histogrammer('total_sessions')

The total_sessions is a right-skewed distribution. The median total number of sessions is 159.6. This is interesting information because, if the median number of sessions in the last month was 56 and the median total sessions was ~160, then it seems that a large proportion of a user's (estimated) total drives might have taken place in the last month. This is something you can examine more closely later.

n_days_after_onboarding

The number of days since a user signed up for the app

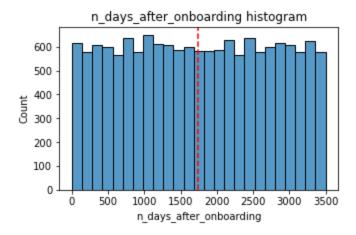

```
In [14]: # Box plot
  plt.figure(figsize=(5,1))
  sns.boxplot(x=df['n_days_after_onboarding'], fliersize=1)
  plt.title('n_days_after_onboarding box plot');
```

n_days_after_onboarding box plot

0 500 1000 1500 2000 2500 3000 3500 n_days_after_onboarding

```
In [15]: # Histogram
histogrammer('n_days_after_onboarding', median_text=False)
```

Median: 1741.0

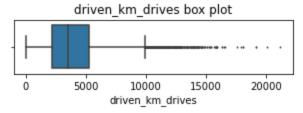

The total user tenure (i.e., number of days since onboarding) is a uniform distribution with values ranging from near-zero to ~3,500 (~9.5 years).

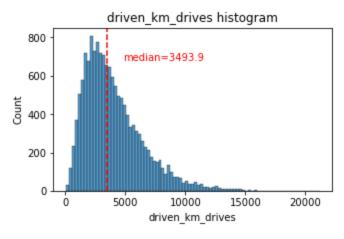

driven_km_drives

Total kilometers driven during the month

```
In [16]: # Box plot
  plt.figure(figsize=(5,1))
  sns.boxplot(x=df['driven_km_drives'], fliersize=1)
  plt.title('driven_km_drives box plot');
```

```
In [17]: # Histogram
histogrammer('driven_km_drives')
```

The number of drives driven in the last month per user is a right-skewed distribution with half the users driving under 3,495 kilometers. As you discovered in the analysis from the

previous course, the users in this dataset drive *a lot*. The longest distance driven in the month was over half the circumferene of the earth.

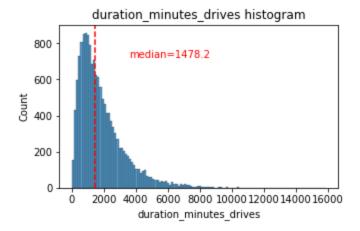

duration_minutes_drives

Total duration driven in minutes during the month

```
In [18]: # Box plot
   plt.figure(figsize=(5,1))
   sns.boxplot(x=df['duration_minutes_drives'], fliersize=1)
   plt.title('duration_minutes_drives box plot');
```

duration_minutes_drives box plot 0 2000 4000 6000 8000 10000 12000 14000 16000 duration minutes drives

```
In [19]: # Histogram
histogrammer('duration_minutes_drives')
```

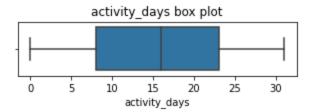

The duration_minutes_drives variable has a heavily skewed right tail. Half of the users drove less than ~1,478 minutes (~25 hours), but some users clocked over 250 hours over the month.

activity_days

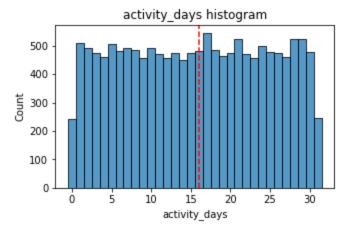

Number of days the user opens the app during the month

```
In [20]: # Box plot
   plt.figure(figsize=(5,1))
   sns.boxplot(x=df['activity_days'], fliersize=1)
   plt.title('activity_days box plot');
```

```
In [21]: # Histogram
histogrammer('activity_days', median_text=False, discrete=True)
```

Within the last month, users opened the app a median of 16 times. The box plot reveals a centered distribution. The histogram shows a nearly uniform distribution of ~500 people opening the app on each count of days. However, there are ~250 people who didn't open the app at all and ~250 people who opened the app every day of the month.

This distribution is noteworthy because it does not mirror the sessions distribution, which you might think would be closely correlated with activity_days.

driving_days

Number of days the user drives (at least 1 km) during the month

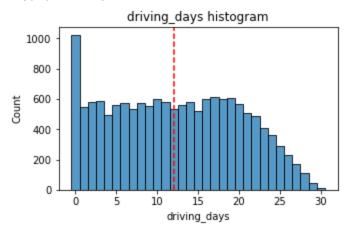

```
In [22]: # Box plot
plt.figure(figsize=(5,1))
sns.boxplot(x=df['driving_days'], fliersize=1)
plt.title('driving_days box plot');
```

```
driving_days box plot

0 5 10 15 20 25 30 driving_days
```

```
In [23]: # Histogram
histogrammer('driving_days', median_text=False, discrete=True)
```

Median: 12.0

The number of days users drove each month is almost uniform, and it largely correlates with the number of days they opened the app that month, except the driving_days distribution tails off on the right.

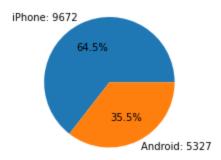

However, there were almost twice as many users (\sim 1,000 vs. \sim 550) who did not drive at all during the month. This might seem counterintuitive when considered together with the information from <code>activity_days</code>. That variable had \sim 500 users opening the app on each of most of the day counts, but there were only \sim 250 users who did not open the app at all during the month and \sim 250 users who opened the app every day. Flag this for further investigation later.

device

The type of device a user starts a session with

This is a categorical variable, so you do not plot a box plot for it. A good plot for a binary categorical variable is a pie chart.

Users by device

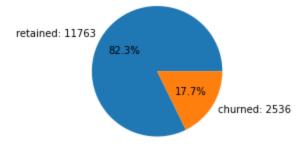

There are nearly twice as many iPhone users as Android users represented in this data.

label

Binary target variable ("retained" vs "churned") for if a user has churned anytime during the course of the month

This is also a categorical variable, and as such would not be plotted as a box plot. Plot a pie chart instead.

Count of retained vs. churned

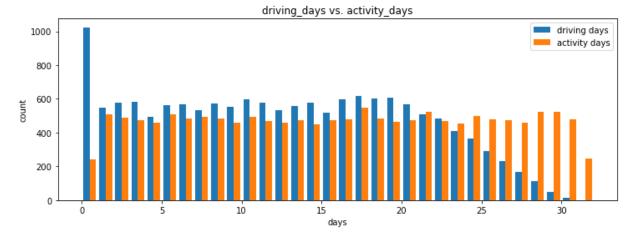

Less than 18% of the users churned.

driving_days vs. activity_days

Because both driving_days and activity_days represent counts of days over a month and they're also closely related, you can plot them together on a single

histogram. This will help to better understand how they relate to each other without having to scroll back and forth comparing histograms in two different places.

Plot a histogram that, for each day, has a bar representing the counts of driving_days and user_days.

As observed previously, this might seem counterintuitive. After all, why are there *fewer* people who didn't use the app at all during the month and *more* people who didn't drive at all during the month?

On the other hand, it could just be illustrative of the fact that, while these variables are related to each other, they're not the same. People probably just open the app more than they use the app to drive—perhaps to check drive times or route information, to update settings, or even just by mistake.

Nonetheless, it might be worthwile to contact the data team at Waze to get more information about this, especially because it seems that the number of days in the month is not the same between variables.

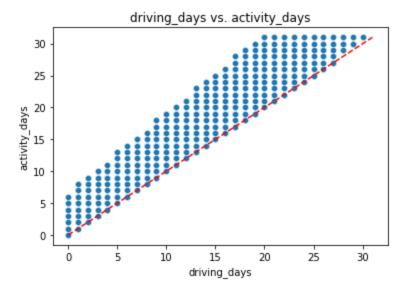

Confirm the maximum number of days for each variable— driving_days and activity_days.

```
In [27]: print(df['driving_days'].max())
    print(df['activity_days'].max())
```

It's true. Although it's possible that not a single user drove all 31 days of the month, it's highly unlikely, considering there are 15,000 people represented in the dataset.

One other way to check the validity of these variables is to plot a simple scatter plot with the x-axis representing one variable and the y-axis representing the other.

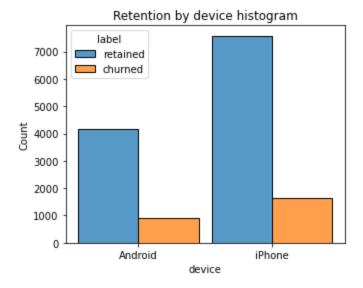

```
In [28]: # Scatter plot
    sns.scatterplot(data=df, x='driving_days', y='activity_days')
    plt.title('driving_days vs. activity_days')
    plt.plot([0,31], [0,31], color='red', linestyle='--');
```

Notice that there is a theoretical limit. If you use the app to drive, then by definition it must count as a day-use as well. In other words, you cannot have more drive-days than activity-days. None of the samples in this data violate this rule, which is good.

Retention by device

Plot a histogram that has four bars—one for each device-label combination—to show how many iPhone users were retained/churned and how many Android users were retained/churned.

The proportion of churned users to retained users is consistent between device types.

Retention by kilometers driven per driving day

In the previous course, you discovered that the median distance driven per driving day last month for users who churned was 608.78 km, versus 247.48 km for people who did not churn. Examine this further.

- 1. Create a new column in df called km_per_driving_day, which represents the mean distance driven per driving day for each user.
- 2. Call the describe() method on the new column.

```
In [30]: # 1. Create `km_per_driving_day` column
         df['km_per_driving_day'] = df['driven_km_drives'] / df['driving_days']
         # 2. Call `describe()` on the new column
         df['km_per_driving_day'].describe()
Out[30]:
                   1.499900e+04
         count
          mean
                            inf
                            NaN
          std
          min
                   3.022063e+00
          25%
                   1.672804e+02
          50%
                   3.231459e+02
          75%
                   7.579257e+02
          max
                            inf
          Name: km_per_driving_day, dtype: float64
```

What do you notice? The mean value is infinity, the standard deviation is NaN, and the max value is infinity. Why do you think this is?

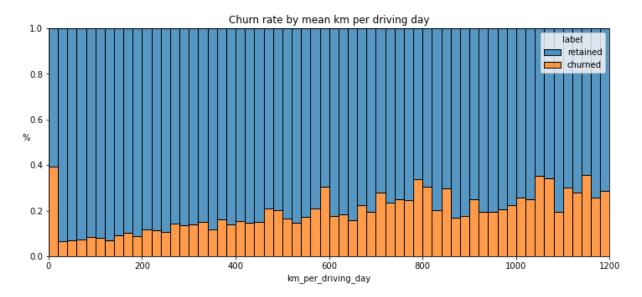

This is the result of there being values of zero in the driving_days column. Pandas imputes a value of infinity in the corresponding rows of the new column because division by zero is undefined.

- 1. Convert these values from infinity to zero. You can use np.inf to refer to a value of infinity.
- 2. Call describe() on the km_per_driving_day column to verify that it worked.

```
In [31]: # 1. Convert infinite values to zero
         df.loc[df['km per driving day']==np.inf, 'km per driving day'] = 0
         # 2. Confirm that it worked
         df['km_per_driving_day'].describe()
Out[31]: count
                  14999.000000
                    578.963113
         mean
                   1030.094384
         std
                       0.000000
         min
         25%
                    136.238895
          50%
                     272.889272
         75%
                     558.686918
                   15420.234110
         max
         Name: km_per_driving_day, dtype: float64
```

The maximum value is 15,420 kilometers *per drive day*. This is physically impossible. Driving 100 km/hour for 12 hours is 1,200 km. It's unlikely many people averaged more than this each day they drove, so, for now, disregard rows where the distance in this column is greater than 1,200 km.

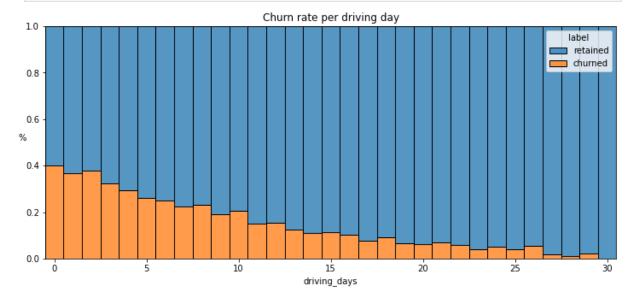

Plot a histogram of the new km_per_driving_day column, disregarding those users with values greater than 1,200 km. Each bar should be the same length and have two colors, one color representing the percent of the users in that bar that churned and the other representing the percent that were retained. This can be done by setting the multiple parameter of seaborn's histplot() function to fill.

The churn rate tends to increase as the mean daily distance driven increases, confirming what was found in the previous course. It would be worth investigating further the reasons for long-distance users to discontinue using the app.

Churn rate per number of driving days

Create another histogram just like the previous one, only this time it should represent the churn rate for each number of driving days.

The churn rate is highest for people who didn't use Waze much during the last month. The more times they used the app, the less likely they were to churn. While 40% of the users who didn't use the app at all last month churned, nobody who used the app 30 days churned.

This isn't surprising. If people who used the app a lot churned, it would likely indicate dissatisfaction. When people who don't use the app churn, it might be the result of dissatisfaction in the past, or it might be indicative of a lesser need for a navigational app. Maybe they moved to a city with good public transportation and don't need to drive anymore.

Proportion of sessions that occurred in the last month

Create a new column percent_sessions_in_last_month that represents the percentage of each user's total sessions that were logged in their last month of use.

```
In [34]: df['percent_sessions_in_last_month'] = df['sessions'] / df['total_sessions']
```

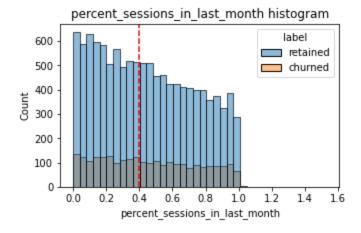

What is the median value of the new column?

```
In [35]: df['percent_sessions_in_last_month'].median()
```

Out[35]: 0.42309702992763176

Now, create a histogram depicting the distribution of values in this new column.

Median: 0.4

Check the median value of the n_days_after_onboarding variable.

```
In [37]: df['n_days_after_onboarding'].median()
```

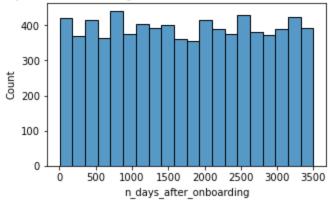

Out[37]: 1741.0

Half of the people in the dataset had 40% or more of their sessions in just the last month, yet the overall median time since onboarding is almost five years.

Make a histogram of n_days_after_onboarding for just the people who had 40% or more of their total sessions in the last month.

```
In [38]: # Histogram
  data = df.loc[df['percent_sessions_in_last_month']>=0.4]
  plt.figure(figsize=(5,3))
  sns.histplot(x=data['n_days_after_onboarding'])
  plt.title('Num. days after onboarding for users with >=40% sessions in last
```

Num. days after onboarding for users with >=40% sessions in last month

The number of days since onboarding for users with 40% or more of their total sessions occurring in just the last month is a uniform distribution. This is very strange. It's worth asking Waze why so many long-time users suddenly used the app so much in the last month.

Task 3b. Handling outliers

The box plots from the previous section indicated that many of these variables have outliers. These outliers do not seem to be data entry errors; they are present because of the right-skewed distributions.

Depending on what you'll be doing with this data, it may be useful to impute outlying data with more reasonable values. One way of performing this imputation is to set a threshold based on a percentile of the distribution.

To practice this technique, write a function that calculates the 95th percentile of a given column, then imputes values > the 95th percentile with the value at the 95th percentile. such as the 95th percentile of the distribution.

```
In [39]: def outlier_imputer(column_name, percentile):
    # Calculate threshold
    threshold = df[column_name].quantile(percentile)
```

```
# Impute threshold for values > than threshold
df.loc[df[column_name] > threshold, column_name] = threshold
print('{:>25} | percentile: {} | threshold: {}'.format(column_name, percentile)
```

Next, apply that function to the following columns:

- sessions
- drives
- total sessions
- driven_km_drives
- duration_minutes_drives

In [41]: df.de	scribe()		
----------------	----------	--	--

Out[41]:		ID	sessions	drives	total_sessions	n_days_after_onbo
	count	14999.000000	14999.000000	14999.000000	14999.000000	14999.0
	mean	7499.000000	76.568705	64.058204	184.031320	1749.8
	std	4329.982679	67.297958	55.306924	118.600463	1008.
	min	0.000000	0.000000	0.000000	0.220211	4.0
	25%	3749.500000	23.000000	20.000000	90.661156	878.0
	50%	7499.000000	56.000000	48.000000	159.568115	1741.0
	75%	11248.500000	112.000000	93.000000	254.192341	2623.5
	max	14998.000000	243.000000	201.000000	454.363204	3500.0

Conclusion

Analysis revealed that the overall churn rate is \sim 17%, and that this rate is consistent between iPhone users and Android users.

Perhaps you feel that the more deeply you explore the data, the more questions arise. This is not uncommon! In this case, it's worth asking the Waze data team why so many

users used the app so much in just the last month.

Also, EDA has revealed that users who drive very long distances on their driving days are *more* likely to churn, but users who drive more often are *less* likely to churn. The reason for this discrepancy is an opportunity for further investigation, and it would be something else to ask the Waze data team about.

Task 4a. Results and evaluation

Having built visualizations in Python, what have you learned about the dataset? What other questions have your visualizations uncovered that you should pursue?

Pro tip: Put yourself in your client's perspective. What would they want to know?

Use the following code fields to pursue any additional EDA based on the visualizations you've already plotted. Also use the space to make sure your visualizations are clean, easily understandable, and accessible.

Ask yourself: Did you consider color, contrast, emphasis, and labeling?

I have learned

- There is missing data in the user churn label, so we might need further data processing before further analysis.
- There are many outlying observations for drives, so we might consider a variable transformation to stabilize the variation.
- The number of drives and the number of sessions are both strongly correlated, so they might provide redundant information when we incorporate both in a model.
- On average, retained users have fewer drives than churned users.

My other questions are

- How does the missingness in the user churn label arise?
- Who are the users with an extremely large number of drives? Are they ridesharing drivers or commercial drivers?
- Why do retained users have fewer drives than churned users? Is it because churned users have a longer history of using the Waze app?
- What is the user demographic for retained users and churned users?

My client would likely want to know ...

- What are the key variables associated with user churn?
- Can we implement policies to reduce user churn?

Use the following two code blocks (add more blocks if you like) to do additional EDA you feel is important based on the given scenario.

```
df['monthly drives per session ratio'] = (df['drives']/df['sessions'])
In [42]:
In [43]: df.head(10)
Out[43]:
             ID

```

Task 4b. Conclusion

Now that you've explored and visualized your data, the next step is to share your findings with Harriet Hadzic, Waze's Director of Data Analysis. Consider the following questions as you prepare to write your executive summary. Think about key points you may want to share with the team, and what information is most relevant to the user churn project.

Questions:

1. What types of distributions did you notice in the variables? What did this tell you about the data?

Nearly all the variables were either very right-skewed or uniformly distributed. For the right-skewed distributions, this means that most users had values in the lower end of the range for that variable. For the uniform distributions, this means that users were generally equally likely to have values anywhere within the range for that variable.

2. Was there anything that led you to believe the data was erroneous or problematic in any way?

Most of the data was not problematic, and there was no indication that any single variable was completely wrong. However, several variables had

highly improbable or perhaps even impossible outlying values, such as driven_km_drives. Some of the monthly variables also might be problematic, such as activity_days and driving_days, because one has a max value of 31 while the other has a max value of 30, indicating that data collection might not have occurred in the same month for both of these variables.

3. Did your investigation give rise to further questions that you would like to explore or ask the Waze team about?

Yes. I'd want to ask the Waze data team to confirm that the monthly variables were collected during the same month, given the fact that some have max values of 30 days while others have 31 days. I'd also want to learn why so many long-time users suddenly started using the app so much in just the last month. Was there anything that changed in the last month that might prompt this kind of behavior?

4. What percentage of users churned and what percentage were retained?

Less than 18% of users churned, and ~82% were retained.

5. What factors correlated with user churn? How?

Distance driven per driving day had a positive correlation with user churn. The farther a user drove on each driving day, the more likely they were to churn. On the other hand, number of driving days had a negative correlation with churn. Users who drove more days of the last month were less likely to churn.

6. Did newer uses have greater representation in this dataset than users with longer tenure? How do you know?

No. Users of all tenures from brand new to ~10 years were relatively evenly represented in the data. This is borne out by the histogram for n_days_after_onboarding, which reveals a uniform distribution for this variable.
